Contents

Continuous Random Variables

- Discrete data are data with a **finite** or **countably infinite** number of possible outcomes. For example: the number of students with blood group AB in MAT2377; the number of Bernoulli trials until observing the first success.

- Continuous data are data which come from a continuous interval of possible outcomes. It means that continuous data are with **uncountably infinitely many outcomes**. For example: the weight of a randomly selected student; the amount of rain that falls in a randomly selected storm.

- In the discrete case, the probability mass function $f_X(x) = P(X = x)$ was the main object of interest. In the continuous case, the analogous role is played by the **probability density function** (**p.d.f**.), still denoted by $f_X(x)$, but $f_X(x) \neq P(X = x)$.

- How do we approach probabilities where there there are **uncountably infinitely many outcomes**, such as one might encounter if X represents the height of an individual in the population, for instance (e.g., the outcomes reside in a continuous interval on the real line)?

- What's the probability that a randomly selected person is 6 feet tall?

C.D.F and P.D.F

The **(cumulative) distribution function** (c.d.f.) of any such random variable X is still defined by

$$\boxed{F_X(x) = P(X \leq x)\,,}$$

is a function of a real value variable x; but $P(X \leq x)$ is not simply computed by adding a few terms of the form $P(X = x_i)$. Note that

$$\boxed{\lim_{x \to -\infty} F_X(x) = 0 \quad \text{and} \quad \lim_{x \to +\infty} F_X(x) = 1.}$$

We can describe the **distribution** of the random variable X *via* the following relationship between $f_X(x)$ and $F_X(x)$:

$$\boxed{f_X(x) = \frac{d}{dx} F_X(x).}$$

Area Under a Curve

For any $a < b$, we have

$$\boxed{P\left(a < X \leq b\right) = F_X(b) - F_X(a) = \int_a^b f_X(x)\,dx}$$

Because, from $\{X \leq b\} = \{X \leq a\} \cup \{a < X \leq b\}$, we have

$$P\left(X \leq b\right) = P\left(X \leq a\right) + P\left(a < X \leq b\right).$$

This implies that

$$\begin{aligned} P\left(a < X \leq b\right) &= P\left(X \leq b\right) - P\left(X \leq a\right) \\ &= F_X(b) - F_X(a) = \int_a^b f_X(x)\,dx \end{aligned}$$

Probability Density Functions (p.d.f.)

The **probability density function** (p.d.f.) of a continuous random variable X is an **integrable** function $f_X : X(\mathcal{S}) \to \mathbb{R}$ such that

- $\boxed{\text{f}_X(x) > 0 \text{ for all } x \in X(\mathcal{S}) \text{ and } \lim_{x\to\pm\infty} f_X(x) = 0}$;
- $\boxed{\int f_X(x)\,dx = 1}$;

- for any event $A = (a, b) = \{X | a < X < b\}$,

$$P(A) = P((a, b)) = \int_a^b f_X(x)\,dx;$$

- for any x,

$$\boxed{F_X(x) = P(X \leq x) = \int_{-\infty}^{x} f_X(t)\,dt}$$

- for any x,

$$\boxed{P(X > x) = 1 - P(X \leq x) = 1 - F_X(x) = \int_x^{\infty} f_X(t)\,dt}$$

- for any $a, b \in \mathbb{R}$,

$$\boxed{\begin{aligned} P(a < X < b) &= P(a \le X < b) = P(a < X \le b) = P(a \le X \le b) \\ &= F_X(b) - F_X(a) = \int_a^b f(x)\,dx. \end{aligned}}$$

- for any $a \in \mathbb{R}$,

$$\boxed{P(X = a) = \lim_{\Delta \to 0} P(a \le X \le a + \Delta) = \lim_{\Delta \to 0} \int_a^{a+\Delta} f_X(x)\,dx = 0.}$$

Examples:

1. Assume that X has the following p.d.f.

$$f_X(x) = \begin{cases} 0 & \text{if } x < 0 \\ x/2 & \text{if } 0 \leq x \leq 2 \\ 0 & \text{if } x > 2 \end{cases} \qquad \text{(note that } \textstyle\int_0^2 f(x)\,dx = 1\text{).}$$

The corresponding c.d.f. is given by:

$$\begin{aligned} F_X(x) &= P(X \leq x) = \textstyle\int_{-\infty}^{x} f_X(t)\,dt \\ &= \begin{cases} 0 & \text{if } x < 0 \\ 1/2 \cdot \int_0^x t\,dt = 1/2 \cdot [t^2/2]_0^x = x^2/4 & \text{if } 0 < x < 2 \\ 1 & \text{if } x \geq 2 \end{cases} \end{aligned}$$

2. What is the probability of the event $A = \{0.5 < X < 1.5\}$?

Solution: we need to evaluate

$$P(A) = P(0.5 < X < 1.5) = F_X(1.5) - F_X(0.5) = \frac{(1.5)^2}{4} - \frac{(0.5)^2}{4} = \frac{1}{2}.$$

3. What is the probability of the event $B = \{X = 1\}$?

Solution: we need to evaluate

$$P(B) = P(X = 1) = P(1 \leq X \leq 1) = F_X(1) - F_X(1) = 0.$$

This is unexpected: even though $f_X(1) = 0.5 \neq 0$, $P(X = 1) = 0$! The probability that a continuous random variable X take on any particular single value is nil.

4. Assume that, for some $\lambda > 0$, X has the following p.d.f.:

$$f_X(x) = \begin{cases} \lambda \exp(-\lambda x) & \text{if } x \geq 0 \\ 0 & \text{if } x < 0 \end{cases} \qquad \text{(is } \int_{-\infty}^{\infty} f(x)\,dx = 1\text{?)}$$

What is the probability that $X > 10.2$?

Solution: the corresponding c.d.f. is given by:

$$F_X(x;\lambda) = P_\lambda(X \leq x) = \int_{-\infty}^{x} f_X(t)\,dt = \begin{cases} 0 & \text{if } x < 0 \\ \lambda \int_0^x \exp(-\lambda t)\,dt & \text{if } x \geq 0 \end{cases}$$

$$= \begin{cases} 0 & \text{if } x < 0 \\ [-\exp(-\lambda t)]_0^x = 1 - \exp(-\lambda x) & \text{if } x \geq 0 \end{cases}$$

Then

$$P(X > 10.2) = 1 - F_X(10.2; \lambda) = 1 - [1 - \exp(-10.2\lambda)] = \exp(-10.2\lambda)$$

is a function of the **distribution parameter** λ itself:

λ	$P_\lambda(X > 10.2)$

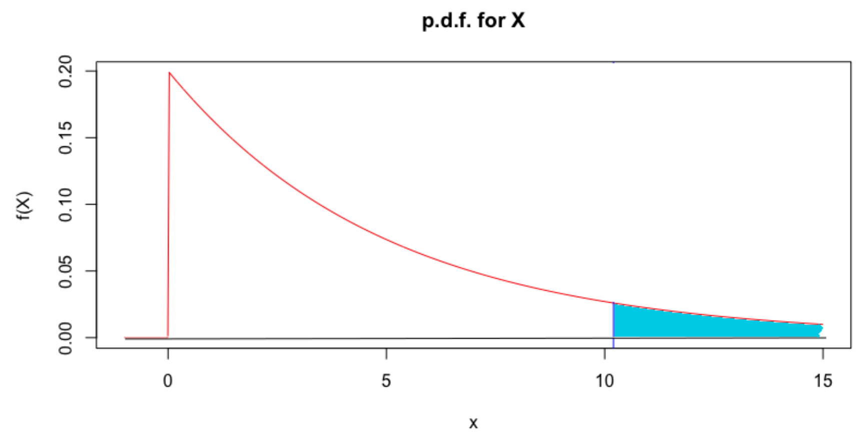
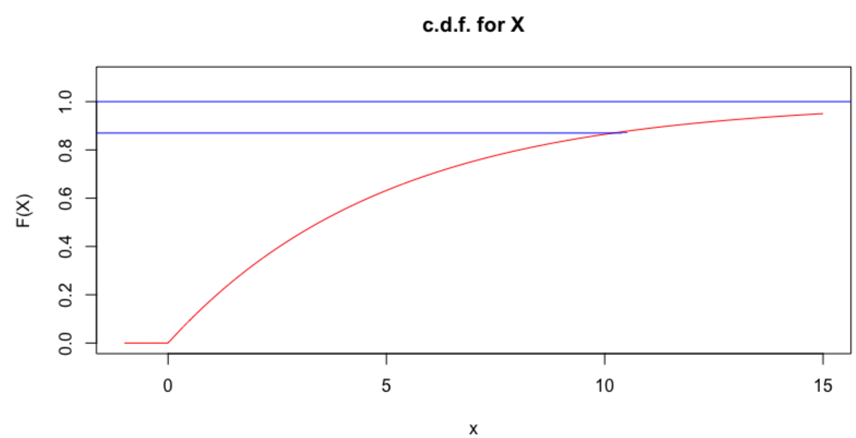
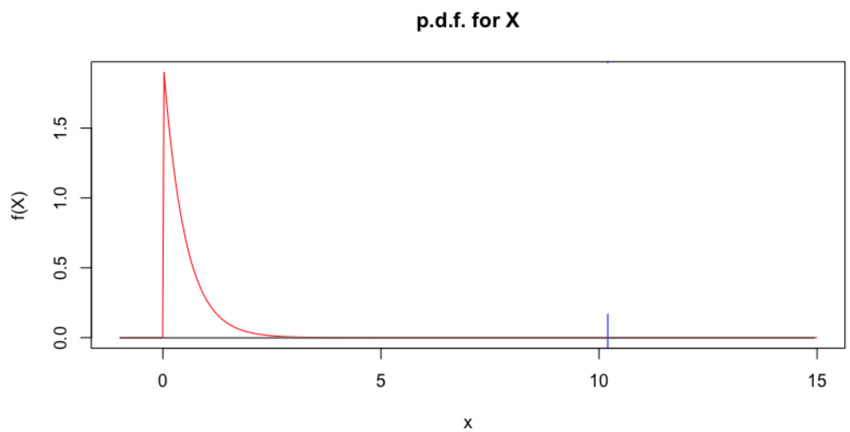
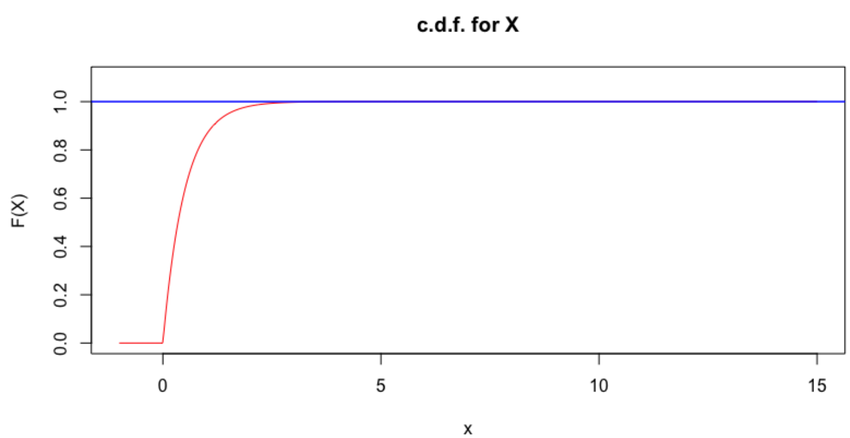
$$\lambda = 0.2$$





$$\lambda = 0.2,\ P_{0.2}(X > 10.2) \approx 0.1300$$





$$\lambda = 2,\ P_2(X > 10.2) \approx 1.38 \times 10^{-9}$$

Expectation of Continuous Random Variables

For a continuous random variable X with p.d.f. $f_X(x)$, the **expectation** of X is defined as

$$\boxed{\mathrm{E}[X] = \int_{-\infty}^{\infty} x f_X(x)\, dx\, .}$$

In a similar way to the discrete case, for any function $h(X)$, we have

$$\boxed{\mathrm{E}\left[h(X)\right] = \int_{-\infty}^{\infty} h(x) f_X(x)\, dx\, .}$$

Note that the **expectation exists if the integral exists**!

Examples:

1. Find the expected value of X in the example 1, above.

   Solution: we need to evaluate

$$\begin{aligned}\mathrm{E}[X] &= \int_{-\infty}^{\infty} x f_X(X)\,dx = \int_0^2 x f_X(x)\,dx = \int_0^2 x \cdot x/2\,dx \\ &= \int_0^2 \frac{x^2}{2}\,dx = \left[\frac{x^3}{6}\right]_{x=0}^{x=2} = \frac{4}{3}.\end{aligned}$$

2. What about X^2?

   Solution: we have $\mathrm{E}[X^2] = \int_0^2 \frac{x^3}{2}\,dx = 2.$

Variance of Continuous Random Variables

In a similar way to the discrete case, the **mean** of X is defined to be $\mathrm{E}[X]$, and the **variance** and **standard deviation** of X are, as before,

$$\boxed{\mathrm{Var}[X] = \mathrm{E}\left[(X - \mathrm{E}(X))^2\right] = \mathrm{E}[X^2] - \mathrm{E}^2[X]\,,}$$

and

$$\boxed{\mathrm{SD}[X] = \sqrt{\mathrm{Var}[X]}\,.}$$

As in the discrete case, if X, Y are continuous random variables, and $a, b \in \mathbb{R}$,

$$\begin{aligned}
\mathrm{E}[aY + bX] &= a\mathrm{E}[Y] + b\mathrm{E}[X] \\
\mathrm{Var}[a + bX] &= b^2\mathrm{Var}[X] \\
\mathrm{SD}[a + bX] &= |b|\mathrm{SD}[X]
\end{aligned}$$

Standard Normal Distribution

An **very** important example of continuous distributions is that of the special probability distribution function

$$\boxed{\phi(z) = \frac{1}{\sqrt{2\pi}} e^{-z^2/2}\,.}$$

The corresponding cumulative distribution function is denoted by

$$\boxed{\Phi(z) = P(Z \leq z) = \textstyle\int_{-\infty}^{z} \phi(t)\,dt\,.}$$

A random variable Z with this c.d.f. is said to have a **standard normal distribution**, and we write $Z \sim \mathcal{N}(0,1)$.

The expectation and variance of $Z \sim \mathcal{N}(0,1)$ are

$$\mathrm{E}[Z] = \int_{-\infty}^{\infty} z\,\phi(z)\,dz = \int_{-\infty}^{\infty} z\,\frac{1}{\sqrt{2\pi}}e^{-\frac{1}{2}z^2}\,dz = 0,$$

$$\mathrm{Var}[Z] = \int_{-\infty}^{\infty} z^2\,\phi(z)\,dz = 1, \quad \mathrm{SD}[Z] = \sqrt{\mathrm{Var}[Z]} = \sqrt{1} = 1.$$

Other quantities of interest include:

$$\Phi(0) = P(Z \leq 0) = \frac{1}{2},$$

$$\Phi(-\infty) = 0,\ \Phi(\infty) = 1,$$

$$\Phi(1) = P(Z \leq 1) = \texttt{pnorm(1)} \approx 0.8413, etc.$$

General Normal Random Variable

Let $\sigma > 0$ and $\mu \in \mathbb{R}$. If $Z \sim \mathcal{N}(0,1)$, then

$$\boxed{X = \mu + \sigma Z \sim \mathcal{N}(\mu, \sigma^2).}$$

However, the c.d.f. of X is given by

$$\begin{aligned} F_X(x) &= P(X \leq x) = P(\mu + \sigma Z \leq x) = P\left(Z \leq \frac{x-\mu}{\sigma}\right) \\ &= \Phi\left(\frac{x-\mu}{\sigma}\right). \end{aligned}$$

The p.d.f. of X is then

$$f_X(x) = \frac{d}{dx} F_X(x) = \frac{d}{dx} \Phi\left(\frac{x-\mu}{\sigma}\right) = \frac{1}{\sigma}\phi\left(\frac{x-\mu}{\sigma}\right)$$

Any random variable X with this c.d.f./p.d.f. must satisfy

$$\mathrm{E}[X] = \mu + \sigma \mathrm{E}[Z] = \mu, \quad \mathrm{Var}[X] = \sigma^2 \mathrm{Var}[Z] = \sigma^2 \;\Rightarrow\; \mathrm{SD}[X] = \sigma$$

and is said to be **normal with mean μ and variance σ^2**, denoted by $X \sim \mathcal{N}(\mu, \sigma^2)$.

Every general normal X can be obtained by a linear transformation of the standard normal Z!

$$\boxed{X = \mu + \sigma Z \sim N(\mu, \sigma) \quad \text{if and only if} \quad Z = \frac{X - \mu}{\sigma} \sim \mathcal{N}(0, 1)}$$

Examples (How to use the standard normal table?):

1. Assume that Z represents the standard normal random variable. Evaluate the following probabilities:

   a) $P(Z \leq 0.5) = \Phi(0.5) = 0.6915$

   b) $P(Z < -0.3) = \Phi(-0.3) = 0.3821$

   c) $P(Z > 0.5) = 1 - P(Z \leq 0.5) == 1 - \Phi(0.5) = 1 - 0.6915 = 0.3085,$

   d) $P(0.1 < Z < 0.3) = P(Z < 0.3) - P(Z < 0.1) = \Phi(0.3) - \Phi(0.1) = 0.6179 - 0.5398 = 0.0781,$

   e) $P(-1.2 < Z < 0.3) = P(Z < 0.3) - P(Z < -1.2) = \Phi(0.3) - \Phi(-1.2) = 0.5028.$

2. Suppose that the waiting time (in minutes) for a coffee at 9am is normally distributed with mean 5 and standard deviation 0.5. What is the probability that one such waiting time is at most 6 minutes?

Solution: let X denote the waiting time; then $X \sim \mathcal{N}(5, 0.5^2)$ and the **standardised random variable** is a standard normal:

$$Z = \frac{X-5}{0.5} \sim \mathcal{N}(0,1)\,.$$

The desired probability is

$$P\left(X \le 6\right) = P\left(\frac{X-5}{0.5} \le \frac{6-5}{0.5}\right) = P\left(Z \le \frac{6-5}{0.5}\right) = \Phi\left(\frac{6-5}{0.5}\right)$$
$$= \Phi(2) = P(Z \le 2) \approx 0.9772 \text{ (reading from the table).}$$

3. Suppose that bottles of beer are filled in such a way that the actual volume of the liquid in them (in mL) varies randomly according to a normal distribution with $\mu = 376.1$ and $\sigma = 0.4$. What is the probability that the volume in any randomly selected bottle is less than 375mL?

Solution: let X denote the volume of the liquid in the bottle; then

$$X \sim \mathcal{N}(376.1, 0.4^2) \quad \text{and so} \quad Z = \frac{X - 376.1}{0.4} \sim \mathcal{N}(0,1)\,.$$

The desired probability is

$$P\left(X < 375\right) = P\left(\frac{X - 376.1}{0.4} < \frac{375 - 376.1}{0.4}\right) = P\left(Z < \frac{-1.1}{0.4}\right)$$
$$= P(Z \leq -2.75) = \Phi\left(-2.75\right) \approx 0.003\,.$$

4. If $Z \sim \mathcal{N}(0,1)$, for which values a, b and c do we have

a) $P(Z \leq a) = 0.95$;

b) $P(|Z| \leq b) = P(-b \leq Z \leq b) = 0.99$;

c) $P(|Z| \geq c) = 0.01$.

Solution:

a) From the table we see that

$$P(Z \leq 1.64) \approx 0.9495 \quad \text{and} \quad P(Z \leq 1.65) \approx 0.9505\,.$$

Clearly we must have $1.64 < a < 1.65$; a linear interpolation provides a decent guess at $a \approx 1.645$, although this level of precision is usually not necessary. It is often sufficient to simply present the initial interval estimate.

b) Note that

$$P\left(-b \leq Z \leq b\right) = P(Z \leq b) - P(Z < -b)$$

However the p.d.f. $\phi(z)$ is symmetric about $z = 0$, which means that

$$P(Z < -b) = P(Z > b) = 1 - P(Z \leq b),$$

and so that

$$P\left(-b \leq Z \leq b\right) = P(Z \leq b) - [1 - P(Z \leq b)] = 2P(Z \leq b) - 1$$

In the question, $P(-b \leq Z \leq b) = 0.99$, so that

$$2P(Z \leq b) - 1 = 0.99 \;\Rightarrow\; P(Z \leq b) = \frac{1 + 0.99}{2} = 0.995\,;$$

Consulting the table we see that

$$P(Z \leq 2.57) \approx 0.9949 \quad \text{and} \quad P(Z \leq 2.58) \approx 0.9951;$$

linear interpolation suggests taking $b \approx 2.575$.

c) Note that $\{|Z| \geq c\} = \{|Z| < c\}^c$, so we need to find c such that

$$P\left(|Z| < c\right) = 1 - P\left(|Z| \geq c\right) = 0.99.$$

But this is equivalent to

$$P\left(-c < Z < c\right) = P(-c \leq Z \leq c) = 0.99$$

since $|x| < y \Leftrightarrow -y < x < y$, and $P(Z = c) = 0$ for all c. This problem was solved in the preceding example; take $c \approx 2.575$.

Exponential Random Variable

Assume that cars arrive according to a **Poisson process with rate** λ, i.e. the number of cars arriving within a fixed unit time period is a Poisson random variable with parameter λ.

Over a period of time x, we would expect the "number of arrivals N" to follow a Poisson process with parameter λx. Let X be the waiting time to the "first" car arrival. Then

$$\boxed{P(X > x) = 1 - P(X \leq x) = P(N = 0) = \exp(-\lambda x).}$$

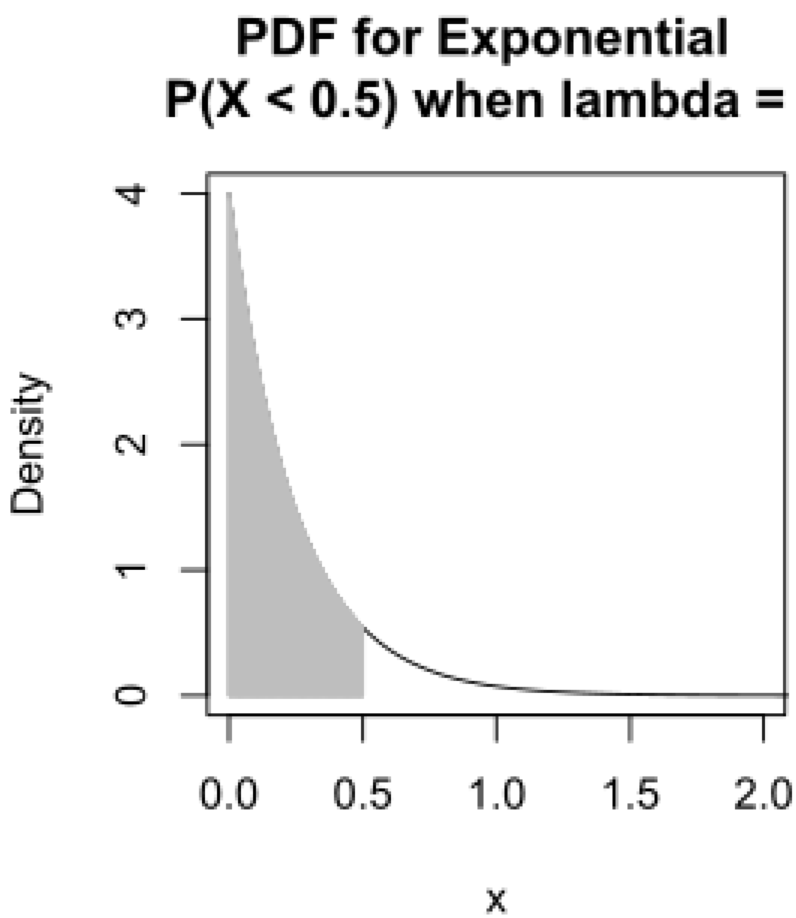
Exponential Random Variable

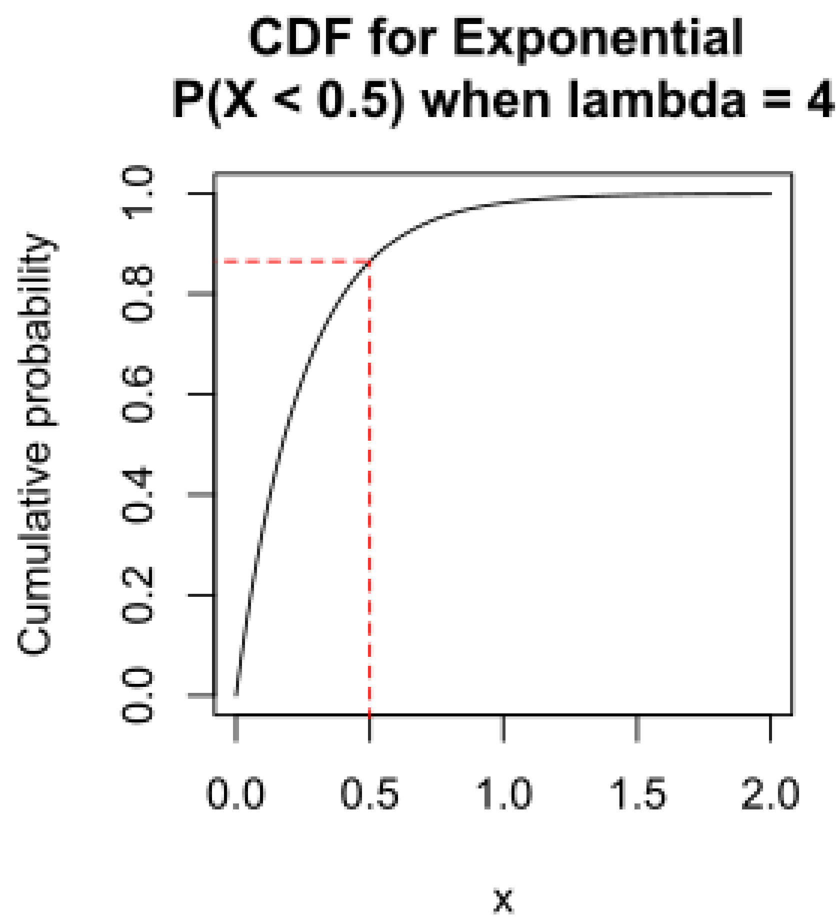
We say that X follows a **exponential distribution** Exp(λ), if its p.d.f. is

$$\boxed{f_X(x) = \begin{cases} \lambda e^{-\lambda x} & \text{for } x \geq 0 \\ 0 & \text{for } x < 0 \end{cases}}$$

If $X \sim$ Exp(λ), then

$$F_X(x) = \begin{cases} 1 - e^{-\lambda x} & \text{for } x \geq 0. \\ 0 & \text{for } x < 0 \end{cases}$$





If $X \sim \text{Exp}(4)$, then $P(X < 0.5) = F_X(0.5) = 1 - e^{-4(0.5)} \approx 0.865.$

Properties of the Exponential Distribution

If $X \sim \text{Exp}(\lambda)$, then:

- $\boxed{\mu_X = \mathrm{E}[X] = 1/\lambda}$;
- $\boxed{\sigma_X^2 = \mathrm{Var}[X] = 1/\lambda^2}$;
- **Memory-Less Property**:

$$\boxed{P(X > s + t \mid X > t) = P(X > s),}$$

- $\text{Exp}(\lambda)$ is the continuous analogue to the **geometric** distribution $\text{Geo}(p)$.

Example:

the lifetime of a certain type of light bulb has an exponential distribution with mean 100 hours (i.e. $\lambda = 1/100$).

1. What is the probability that a light bulb will last at least 100 hours?

   Solution: $X \sim \text{Exp}(1/100)$, so

$$P(X > 100) = 1 - P(X \leq 100) = \exp(-100/100) = e^{-1} \approx 0.3679.$$

2. What is the probability that a light bulb will last at least 100 hours?

   Solution: we are interested in evaluating $P(X > 200|X > 100)$. By the memory-less property,

$$P(X > 200|X > 100) = P(X > 200 - 100) = P(X > 100) \approx 0.3679.$$

3. The manufacturer wants to guarantee that their light bulbs will last at least t hours. What should t be in order to ensure that 90% of the light bulbs will last longer than t hours?

   Solution: we need to find t such that $P(X > t) = 0.9$. In other words, we are looking for t such that

$$0.9 = P(X > t) = 1 - P(X \leq t) = 1 - F_X(t) = e^{-0.01t},$$

   that is

$$\ln 0.9 = -0.01t \quad \Longrightarrow \quad t = -100 \ln 0.9 \approx 10.53605 \text{ hours.}$$

Gamma Random Variable

Assume that cars arrive according to a Poisson process with rate λ. Recall that if X is the waiting time to the first car arrival, then $X \sim \text{Exp}(\lambda)$.

If Y is the waiting time to the k-th arrival, then Y follows a **Gamma distribution** with parameters λ and k, $Y \sim \Gamma(\lambda, k)$, for which the p.d.f. is

$$\boxed{f_Y(y) = \begin{cases} 0 & \text{for } y < 0 \\ \dfrac{y^{k-1}}{(k-1)!}\lambda^k e^{-\lambda y} & \text{for } 0 \leq y \end{cases}}$$

$F_Y(y)$ cannot be expressed with elementary functions. We also have

$$\mu_Y = \text{E}[Y] = \frac{k}{\lambda} \quad \text{and} \quad \sigma_Y^2 = \text{Var}[Y] = \frac{k}{\lambda^2}.$$

Examples:

1. Suppose that an average of 30 customers per hour arrive at a shop in accordance with a Poisson process, that is to say, $\lambda = 1/2$ customers arrive on average every minute. What is the probability that the shopkeeper will wait more than 5 minutes before both of the first two customers arrive?

Solution: let Y denote the waiting time in minutes until the second customer arrives. Then $Y \sim \Gamma(1/2, 2)$ and

$$
\begin{aligned}
P(Y > 5) &= \int_5^\infty f(y)dy \\
&= \int_5^\infty \frac{y^{2-1}}{(2-1)!}(1/2)^2 e^{-y/2}\,dy = \int_5^\infty \frac{ye^{-y/2}}{4}\,dy \\
&= \frac{1}{4}\left[-2ye^{-y/2} - 4e^{-y/2}\right]_5^\infty = \frac{7}{2}e^{-5/2} \approx 0.287.
\end{aligned}
$$

2. Telephone calls arrive at a switchboard at a mean rate of $\lambda = 2$ per minute, according to a Poisson process. Let Y be the waiting time until the 5th call arrives. What is the p.d.f., the mean, and the variance of Y?

Solution: we have

$$f_Y(y) = \frac{2^5 y^4}{4!} e^{-2y}, \text{ for } 0 \leq y < \infty, \quad \mathrm{E}[Y] = \frac{5}{2}, \quad \mathrm{Var}[Y] = \frac{5}{4}.$$

The Gamma distribution can be extended to cases where $r > 0$ is not an integer by replacing $(r-1)!$ by $\Gamma(r) = \int_0^\infty t^{r-1} e^{-t}\, dt$.

The exponential and the χ^2 distributions (we will discuss that one later) are special cases of $\Gamma(\lambda, r)$: Exp$(\lambda) = \Gamma(\lambda, 1)$ and $\chi^2(r) = \Gamma(1/2, r)$.

Joint Distributions

Let X, Y be two continuous random variables. The **joint probability distribution function** (joint p.d.f.) of X, Y is a function $f(x, y)$ satisfying

1. $f(x, y) \geq 0$, for all x, y;
2. $\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} f(x, y)\, dx dy = 1$.

For any $A \subseteq \mathbb{R}^2$, $P(A) = \int\int_A f(x, y)\, dx dy$. This implies that $P(A)$ is the volume of the solid over the region A in the xy plane bounded by the surface $z = f(x, y)$.

Examples:

1. There are 8 similar chips in a bowl: three marked $(0, 0)$, two marked $(1, 0)$, two marked $(0, 1)$ and one marked $(1, 1)$. A player selects a chip at random and is given the sum of the two coordinates in dollars.

   a) What is the joint probability mass function of X_1, and X_2?
   Solution: let X_1 and X_2 represent the coordinates; we have

$$f(x_1, x_2) = \frac{3 - x_1 - x_2}{8}, \quad x_1, x_2 = 0, 1.$$

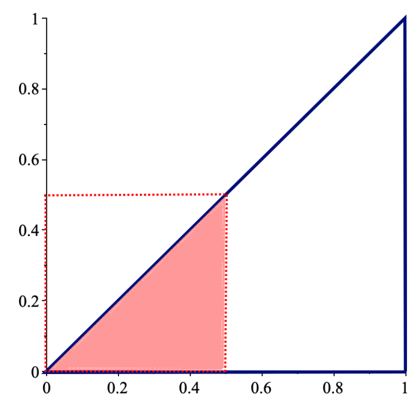
a) What is the expected pay-off for this game?
Solution: the pay-off is simply $X_1 + X_2$. The expected pay-off is thus

$$\begin{aligned}
\mathrm{E}[X_1 + X_2] &= \sum_{x_1=0}^{1} \sum_{x_2=1}^{0} (x_1 + x_2) f(x_1, x_2) \\
&= 0 \cdot \frac{3}{8} + 1 \cdot \frac{2}{8} + 1 \cdot \frac{2}{8} + 2 \cdot \frac{1}{8} \\
&= 0.75.
\end{aligned}$$

2. Let X and Y have joint p.d.f.

$$f(x,y) = 2, \quad 0 \leq y \leq x \leq 1.$$

a) What is the support of $f(x,y)$?
Solution: the support is the set $S = \{(x,y) : 0 \leq y \leq x \leq 1\}$, a triangle in the xy plane bounded by the $x-$axis, the line $y = 1$, and the line $y = x$. The support is the blue triangle shown below.



b) What is $P(0 \leq X \leq 0.5, 0 \leq Y \leq 0.5)$?
Solution: we need to evaluate the integral over the shaded area:

$$\begin{aligned}
P(0 \leq X \leq 0.5, 0 \leq Y \leq 0.5) &= P(0 \leq X \leq 0.5, 0 \leq Y \leq X) \\
&= \int_0^{0.5} \int_0^x 2\, dydx = \int_0^{0.5} [2y]_{y=0}^{y=x}\, dx \\
&= \int_0^{0.5} 2x\, dx = 1/4.
\end{aligned}$$

c) What are the marginal probabilities $f_X(x)$ and $f_Y(y)$?
Solution: we get

$$f_X(x) = \int_{-\infty}^{\infty} f(x,y)\,dy = \int_{y=0}^{y=x} 2\,dy = [2y]_{y=0}^{y=x} = 2x, \quad 0 \le x \le 1$$

and

$$\begin{aligned} f_Y(y) &= \int_{-\infty}^{\infty} f(x,y)\,dx = \int_{x=y}^{x=1} 2\,dx \\ &= [2x]_{x=y}^{x=1} = 2 - 2y, \quad 0 \le y \le 1. \end{aligned}$$

d) Compute $\mathrm{E}[X]$, $\mathrm{E}[Y]$, and $\mathrm{E}[Y^2]$
Solution: we have

$$\begin{aligned}\mathrm{E}[X] &= \iint_S x f(x,y)\,dA = \int_0^1 \int_0^x 2x\,dydx = \int_0^1 [2xy]_{y=0}^{y=x}\,dx \\ &= \int_0^1 2x^2\,dx = \left[\frac{2}{3}x^3\right]_0^1 = \frac{2}{3};\end{aligned}$$

$$\begin{aligned}\mathrm{E}[Y] &= \iint_S y f(x,y)\,dA = \int_0^1 \int_y^1 2y\,dxdy = \int_0^1 [2xy]_{x=y}^{x=1}\,dy \\ &= \int_0^1 (2y - 2y^2)\,dy = \left[y^2 - \frac{2}{3}y^3\right]_0^1 = \frac{1}{3};\end{aligned}$$

$$\begin{aligned}\mathrm{E}[Y^2] &= \iint_S y^2 f(x,y)\,dA = \int_0^1 \int_y^1 2y^2\,dxdy = \int_0^1 \left[2xy^2\right]_{x=y}^{x=1}\,dy \\ &= \int_0^1 (2y - 2y^3)\,dy = \left[\frac{2}{3}y^3 - \frac{1}{2}y^4\right]_0^1 = \frac{1}{6}\end{aligned}$$

e) Are X and Y independent?
Solution: they are not independent as the support of the joint p.d.f. is not rectangular.

Normal Approximation of the Binomial Distribution

If $X \sim \mathcal{B}(n,p)$ then we may interpret X as a sum of **independent and identically distributed** random variables

$$X = I_1 + I_2 + \cdots + I_n \text{ where each } I_i \sim \mathcal{B}(1,p)\,.$$

Thus, according to the **Central Limit Theorem** (more on this later), for large n, we have

$$\boxed{\frac{X - np}{\sqrt{np(1-p)}} \overset{\text{approx}}{\sim} \mathcal{N}(0,1)\,,}$$

i.e. for large n if $X \overset{\text{exact}}{\sim} \mathcal{B}(n,p)$ then $X \overset{\text{approx}}{\sim} \mathcal{N}(np, np(1-p))$.

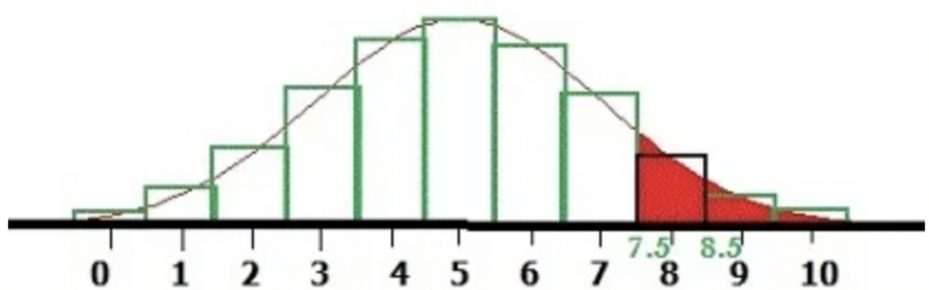
Continuity Correction

Let $X \sim \mathcal{B}(n,p)$. Recall that $\mathrm{E}[X] = np$ and $\mathrm{Var}[X] = np(1-p)$. If n is large, we may approximate X by a normal random variable in the following way:

$$P(X \le x) = P(X < x + 0.5) = P\left(Z < \frac{x - np + 0.5}{\sqrt{np(1-p)}}\right)$$

and

$$P(X \ge x) = P(X > x - 0.5) = P\left(Z > \frac{x - np - 0.5}{\sqrt{np(1-p)}}\right).$$



Example:

suppose $X \sim \mathcal{B}(36, 0.5)$. Provide a normal approximation to the probability $P(X \leq 12)$. *Note:* For $n = 36$ the binomial probabilities are not available in the textbook tables.

Solution: since $\mathrm{E}[X] = 36 \times 0.5 = 18$ and $\mathrm{Var}[X] = 36 \times 0.5 \times 0.5 = 9$,

$$P(X \leq 12) = P\left(\frac{X - 18}{3} \leq \frac{12 - 18 + 0.5}{3}\right)$$
$$\overset{\text{norm.approx'n}}{\approx} \Phi(-1.83) \overset{\text{table}}{\approx} 0.033\,.$$

Compare this to the R value of `pbinom(12, 36, 0.5)` $= 0.0326$.

Computing Binomial Probabilities

We thus have at least 3 ways to compute (or approximate) binomial probabilities:

- Use the exact formula: if $X \sim \mathcal{B}(n,p)$ then for each $x = 0, 1, \ldots, n$, $P(X = x) = \binom{n}{x} p^x (1-p)^{n-x}$;
- Use tables: if $n \leq 15$ and p is one of 0.1, 0.2,$\ldots$, 0.9, then the CDF is in the textbook (must express desired probability in terms of CDF, i.e. in form $P(X \leq x)$ first), i.e.

$$P(X < 3) = P(X \leq 2); \qquad P(X = 7) = P(X \leq 7) - P(X \leq 6)\,;$$

$$P(X > 7) = 1 - P(X \leq 7); \qquad P(X \geq 5) = 1 - P(X \leq 4) \text{ etc.}$$

- Use normal approximation: the suggested "rule of thumb " in the binomial case is: if np **and** $n(1-p)$ **are both** ≥ 5, the normal approximation $X \sim \mathcal{N}(np, np(1-p))$

$$P(X \leq x) \approx \Phi\left(\frac{x + 0.5 - np}{\sqrt{np(1-p)}}\right)$$

$$P(X \geq x) \approx 1 - \Phi\left(\frac{x - 0.5 - np}{\sqrt{np(1-p)}}\right)$$

for $x = 0, 1, \ldots, n$ should provide a decent approximation.

Summary

X	Example	$f(x)$	Domain	$\mathrm{E}[X]$	$\mathrm{Var}[X]$
Uniform	Select a point at random from $[a, b]$	$\dfrac{1}{b-a}$	$a \le x \le b$	$\dfrac{a+b}{2}$	$\dfrac{(b-a)^2}{12}$
Normal	Meas. errors; children heights; breaking strengths, etc.	$\dfrac{\exp(-(x-\mu)^2/2\sigma^2)}{\sigma\sqrt{2\pi}}$	$-\infty < x < \infty$	μ	σ^2
Exponential	Waiting time to first arrival in a Poisson process with rate λ	$\lambda e^{-\lambda x}$	$0 \le x < \infty$	$\dfrac{1}{\lambda}$	$\dfrac{1}{\lambda^2}$
Gamma	Waiting time to rth arrival in a Poisson process with rate λ	$\dfrac{x^{r-1}}{(r-1)!}\lambda^r e^{-\lambda x}$	$0 \le x < \infty$	$\dfrac{r}{\lambda}$	$\dfrac{r}{\lambda^2}$

Summary

$X \sim B(n,p)$ and $np > 5$ and $n(1-p) > 5$:

$$P(X \leq x) = P(X < x + 0.5) = P\left(Z < \frac{x - np + 0.5}{\sqrt{np(1-p)}}\right)$$

and

$$P(X \geq x) = P(X > x - 0.5) = P\left(Z > \frac{x - np - 0.5}{\sqrt{np(1-p)}}\right).$$
